#### 1 Generally Useful Math

### **Trig Properties**

$$\sin^2 x + \cos^2 x = 1 \qquad \frac{d}{dx} \sin x = \cos x$$

$$\tan x = \frac{\sin x}{\cos x} \qquad \frac{d}{dx} \cos x = -\sin x$$

$$\frac{d}{dx} \tan x = \sec^2 x \qquad \frac{d}{dx} \cot x = -\csc^2 x$$

$$\frac{d}{dx} \arcsin x = \frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx} \arccos x = \frac{-1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx} \arctan x = \frac{1}{1+x^2}$$

# Log & Exp Properties

$$\frac{x}{dx}b^{x} = b^{x} \ln x \qquad \log(\frac{1}{x}) = -\log x$$

$$\log_{a} x = \frac{\log_{b} x}{\log_{a} x} \qquad \frac{d}{dx}e^{ax} = ae^{ax}$$

$$\frac{d}{dx}a^{x} = a^{x} \ln a \qquad \frac{d}{dx} \ln x = \frac{1}{x}$$

$$x^{0} = 1 \qquad x^{n} \cdot x^{m} = x^{n+m} \qquad x^{-n} = \frac{1}{x^{n}}$$

$$\log_{a} x^{n} = n\log_{a} x \qquad \frac{e^{-nx}}{e^{x}} = e^{-(n+1)x}$$

$$\log_{a}(\frac{x}{y}) = \log_{a} x - \log_{a} y$$

$$\log_{a}(xy) = \log_{a} x + \log_{a} y$$

#### Useful Series

$$r^0 + r^1 + r^2 + r^3 = \frac{r^n - 1}{r - 1}$$
 for an alternating series the following will work to start:  $\sum_{n=0}^{\infty} (-1)^n \text{ or } \sum_{n=0}^{\infty} (-1)^{n+1}$ 

# In Class Terminology

# the relative error formula: $\frac{|x-\hat{x}|}{x}$ x' = f(t, x)

this was represed strangely in class: If x'' = xx' then x''' = xx'' + x'x'

## 2 Base Conversion

### Decimal to Binary

For this simply find the place of the largest binary number that (of the form  $2^n$ ) that is within the number. Successivley subtract these numbers while keeping track of their place to generate the binary number.

### Binary to Decimal

For this notice that each place in the decimal number has a corresponding power of 2. If the decimal number has a floating point then the power is negative counting from zero. This generates a sum of the form:  $2^n + \dots + 2^2 + 2^1 + 2^{-1} + 2^{-2} + \dots + 2^{-m}$ Where n is the most significant digit and m is the least. The  $2^{-1}$  term is the begin-

ning of the floating point numbers.

#### **Binary to Octal**

Simply follow the table: 
$$000 \rightarrow 0.001 \rightarrow 1.002 \rightarrow 2.003 \rightarrow 3.004 \rightarrow 4.005 \rightarrow 5.006 \rightarrow 6.007 \rightarrow 7.000$$

# Binary to Hex

This identical to the Octal method, the Hex symbols range from 0 to F and binary from 0000 to 1111. Simply count up un binary and there is a simple conversi-

### One & Two's Complement

#### 3 IEEE Floating Points **Definitions**

s =signed bit, c =based exponent, F =fraction. The general form for this is  $(-1)^{s} \cdot 2^{c-127} \cdot 1.F$ , for both |s| = 1For single precision: |c| = 8, |F| = 23For double precision: |c| = 11, |F| = 52

### **Converting to IEEE Format**

A number will have the form  $D_n...D_1D_0.F_0F_1...F_m$ , to start we need to shift the values left (normalize) so that the number is now of the form:  $D_n.F_0F_1...F_{m+(n-1)}$ .

### Example

#### **TODO**

# 4 Loss of Significance

### Loss of Precision Theorem

The general form of the theorem is as x and y are floating point numbers such

that x > y > 0, the theorem states that

given:  $2^{-p} \le 1 - \frac{y}{x} \le 2^{-q}$ 

as x approaches z.

there are at most p and at least q digits lost in the subtraction x - y.

practically speaking, we view the equation as: E(x) = f(x) - g(x). If we notice this approaches 0 we have a concern of loss of precision at that point. to find that point we typically view the max loss acceptable

as 1, so we set the euquation to  $\frac{g(x)}{f(x)} = \frac{1}{2}$ .  $K_2 = hf(t + \frac{1}{2}h, x + \frac{1}{2}K_1)$ We find the x = z values that cause the  $K_3 = hf(t + \frac{1}{2}h, x + \frac{1}{2}K_2)$  $E(z) > \frac{1}{2}$  and use a Taylor method there and use the normal formula elsewhere. first, the  $K_n$  values are calculated in suc-

### **Rationalizing Numerators**

In some cases we want to rationalize a numerator to avoid a loss of significance. The general form for radicals in a demonitor is:

$$\sqrt[k]{x^n+r} + c \cdot \frac{\sqrt[k]{x^n+r-c}}{\sqrt[k]{x^n+r-c}} = \frac{x^n+r-2c}{\sqrt[k]{x^n+r-c}}$$

5 Taylor, Maclaurin, & Euler

### 6 Runge-Kutta Methods

## RK4

This is the 4th order (RK4) Runge-Kutta method for the Initial Value Problem (IVP):

$$x(t+h) = x(t)\frac{1}{6}(K_1 + 2K_2 + 2K_3 + K_4)$$
  
where the following are values of  $K_n$ :  
 $K_1 = hf(t,x)$ 

$$K_2 = hf(t + \frac{1}{2}h, x + \frac{1}{2}K_1)$$
  
 $K_2 = hf(t + \frac{1}{2}h, x + \frac{1}{2}K_2)$ 

$$K_3 = hf(t + \frac{1}{2}h, x + \frac{1}{2}K_2)$$
  
 $K_4 = hf(t + h, x + K_3)$ 

We're just avoiding the loss of precision cession. They the  $K_n$  values are filled into the first formula above.
